

Utilizing Business Analytics for Informed Decision-Making in Opening a New Restaurant in Bangalore

1. Introduction

Bangalore is Karnataka's capital and largest city, a state in southern India. It is India's third most populated city, with a metro population of almost 11 million. Bangalore is renowned for its extensive restaurant scene and diversified food culture, providing a gourmet haven for food lovers. In today's competitive restaurant industry, making informed decisions is crucial for the success of a new establishment. With the rapidly expanding restaurant scene in Bangalore, India, choosing the right location, managing prices effectively, and maintaining high levels of customer satisfaction are critical challenges aspiring restaurant owners face. Fortunately, business analytics offers valuable tools and techniques to address these challenges and make data-driven decisions. By leveraging data from sources like Zomato, a popular online food delivery and restaurant discovery platform, restaurant owners can gain insights into the market landscape, customer preferences, and industry trends.

This article explores the application of business analytics in opening a new restaurant in Bangalore. It begins by discussing the dataset obtained from Zomato, which provides comprehensive information about restaurants in the city. The data cleaning process is then outlined, ensuring accuracy and reliability for subsequent analysis. Three critical problems faced by restaurant management are identified: choosing the location and restaurant type, price management, and maintaining customer satisfaction levels.

Using business analytics techniques, each of these problems is examined in detail, providing actionable insights for decision-making. For selecting the optimal location and restaurant type, chi-square test and visualizations like bar charts are employed to identify areas with high restaurant density and understand the association between location and restaurant type. Price management is addressed through market research and analysis of pricing strategies, utilizing chi-square test and line charts to identify the relationship between location and price range. Lastly, how to maintain customer satisfaction levels is explored by analyzing online ratings and reviews, leveraging descriptive statistics and bar charts to gauge customer perception and identify areas for improvement.

By utilizing business analytics in decision-making, aspiring restaurant owners in Bangalore can mitigate risks, maximize their chances of success, and gain a competitive edge in the

vibrant restaurant industry. The insights derived from data analysis enable informed decision-making, helping new restaurants position themselves strategically, set competitive prices, and meet customer expectations. Ultimately, by leveraging the power of business analytics, restaurant owners can make data-driven choices that drive growth, enhance customer satisfaction, and ensure long-term profitability in Bangalore's dynamic and demanding restaurant landscape.

2. Dataset

The dataset used in this analysis was obtained from Zomato, a popular online food delivery and restaurant discovery platform. The dataset was made available on Kaggle for open download and use. The dataset provides comprehensive information about restaurants in Bangalore, including their locations, price range, ratings, reviews, and various other attributes related to the dining experience. The dataset has a total of 56,250 records with 17 unique variables, as shown in Figure 1.

3. Data Cleaning Process

Data cleaning is a crucial step in the business analytics process, involving identifying and rectifying errors, inconsistencies, and missing values in the dataset to ensure its accuracy and reliability for analysis. The cleaning process included removing duplicates, addressing missing data, and standardizing variables for effective data analysis. After removing duplicates and missing values, data of 8,687 restaurants was obtained for the analysis process.

Twelve variables were identified, which are crucial for the data analysis process. They are as followed:

1. Restaurant Name – The name of the restaurant.
2. Delivery – If the restaurant offers delivery service.
3. Rating – The restaurant's rating is out of 5, with the format 'Rating No'/5.
4. Rating (2) – The restaurant's rating out of 5, with the format 'Rating No'.
5. Votes – The number of votes the restaurant has received for the rating.
6. Location – The neighborhood/suburb in which the restaurant is located.
7. Location Code – A unique number given to the restaurant location.

The following figure shows the first 15 records of the cleaned data.

Figure 2

Three problems have been identified that the management may face when opening a new restaurant. These problems are as followed:

1. Choosing the Location & Restaurant Type
2. Price Management
3. Maintaining customer satisfaction levels

Using Business Analytics, the management can successfully overcome these challenges. An in-depth discussion of these problems and their solutions using analytics is discussed below.

4.1 Choosing the Location & Restaurant Type

One of the most crucial factors in a restaurant's success is finding the perfect location, and choosing the wrong location could result in a lack of sales and ultimate failure (Calderón et al., 2021). It is also one of the characteristics that's difficult to change and nearly impossible to overcome (Calderón et al., 2021). By drawing in more customers, a good location can boost a restaurant's competitive advantage and influence the restaurant that customers select (Torlak et al., 2020). According to Self et al., (2015), restaurant failure has long been attributed primarily to bad location decisions. The main problem with picking the wrong location for a restaurant is that after it has opened and sales are lower than expected, the investment in infrastructure or adaptations has already been made and cannot be altered (De Meirleir, 2011, as cited in Calderón et al., 2021). However, even if a restaurant's strategy was poorly planned, a good location might still contribute to its success (Karadeniz, 2009, as referenced in Calderón et al., 2021).

When opening a new restaurant, it is crucial to consider the existing restaurant landscape in the chosen location. Opening a restaurant in an area with an already established restaurant scene can be advantageous, as it indicates a demand for dining options and attracts potential customers (Self et al., 2015). However, it is crucial to choose the type of restaurant carefully based on the location (Prayag et al., 2012). Understanding the preferences and demographics of the target customer base in the area can help in selecting a restaurant type that aligns with their needs and desires (Calderón et al., 2021; Prayag et al., 2012). This strategic alignment between the restaurant type and location can increase the chances of success and customer attraction, even in the presence of competition.

A bar chart can be an effective tool to represent the distribution of restaurants across different locations visually. By plotting the number of restaurants on the y-axis and the locations on the x-axis, the bar chart, as shown in Figure 3, provides a clear comparison of the restaurant density in various suburbs of Bangalore. Management can utilize this information to identify locations with a higher concentration of restaurants, indicating a potential demand for dining options. BTM, Whitefield, and Electronic City were the top three suburbs identified in this

case. These areas suggest a higher likelihood of attracting customers and benefiting from existing foot traffic. By analyzing this bar chart, management can narrow down potential locations for the new restaurant and prioritize those with a significant number of restaurants.

Figure 3

Restaurant Density Bar Chart (Self-drawn using Qlik)

On the other hand, a chi-square test can help identify the relationship between restaurant type and location. This statistical test examines whether there is a significant association between two categorical variables, in this case, restaurant type and location. By analyzing the observed frequencies of restaurant types across different locations and comparing them to the expected frequencies, the chi-square test was able to determine if the distribution of restaurant types is dependent on the location. A $P < 0.05$ was observed in this test, which proves that there is an association between location and restaurant type. This information can guide decision-making when selecting the optimal location based on the desired restaurant type.

Furthermore, a Mekko chart can be used to identify the top restaurant types in the top locations. In this case, the top three locations, BTM, Whitefield, and Electronic City, were used to make the chart (Figure 8), which visually displays the proportion of each restaurant type within these locations. By examining the Mekko chart, management can quickly identify which restaurant types dominate the top locations, providing insights into the competitive landscape and the preferences of customers in those areas. By identifying the top restaurant types in top locations, management can align their selection with customer preferences and market demand, maximizing the chances of success for the new restaurant (Calderón et al., 2021; Prayag et al., 2012).

Restaurant Type Mekko Chart (Self-drawn using Qlik)

4.2 Price Management

Price management is a crucial and challenging decision for new restaurants. Determining the right pricing strategy requires careful consideration of various factors to ensure the restaurant's success. Setting prices too high may deter potential customers, while setting them too low may lead to financial instability or undervaluing the offerings (Liu & Tse, 2018). One of the critical considerations in price management is understanding the target market and its willingness to pay. Conducting market research and analyzing the pricing strategy of already established restaurants can provide insights into the customer's price sensitivity and expectations (Raab et al., 2009). This information allows restaurant owners to select an approximate price range that aligns with the target market's affordability and perceived value (Dominique-Ferreira et al., 2019; Raab et al., 2009).

Moreover, it is important to consider the restaurant's positioning in the market. Factors such as the restaurant's concept, type, and location must be reflected in the pricing strategy (Thielemann et al., 2018). For example, a higher-end fine dining restaurant may justify higher prices by emphasizing premium ingredients and an exceptional dining experience. On the other hand, a casual eatery might opt for a more affordable pricing structure to attract a larger customer base (Liu & Tse, 2018). Carefully selecting an appropriate price range not only attracts the target customers but also contributes to the restaurant's profitability. Overall, Price management poses a significant challenge for new restaurants. By understanding the target market, considering the restaurant's positioning, and carefully selecting an approximate price range, management can establish a pricing strategy that attracts customers, reflects the restaurant's value proposition, and supports long-term success (Dominique-Ferreira et al., 2019; Liu & Tse, 2018; Thielemann et al., 2018).

A chi-square test can be utilized to identify the relationship between restaurant location and the approximate price range of restaurants. This statistical test examines the association between two categorical variables and can help determine if there is a significant relationship or dependence between these variables of interest. In this case, the chi-square test can assess whether there is a relationship between the location of restaurants and the price range they offer.

By running the chi-square test on the location and approximate price range of existing restaurants from the given data, management can analyze the observed frequencies and expected frequencies of different price ranges across various locations. After successfully running the chi-square test, a p-value <0.05 was observed, which indicates that there is statistical significance between the restaurant's location and its price range.

Figure 9

Abstract

Chi-square Formula and Test result

100

can assist the management in identifying the appropriate price range for a new restaurant and aid in setting the appropriate price range for a new restaurant. The x-axis represents the number of restaurants on the x-axis and the average price range on the y-axis. The chart represents the approximate price ranges of all restaurants in the city. The chart shows that the price range of 300-500 is the most common price range for all restaurants.

Approximate Price Range Line Chart (Self-drawn using Qlik)

Analyzing the line chart allows management to identify pricing trends and patterns in different locations. They can observe the average price ranges for restaurants in various areas and make informed decisions about setting a competitive and profitable price range for their new establishment. The line chart helps management understand the pricing landscape, take into account the local market conditions, and strike a balance between affordability for customers and profitability for the restaurant.

Figure 14

Location-wise approximate price range Line Chart (Self-drawn using Qlik)

By using both the chi-square test to identify the relationship between location and price range and the line chart to analyze the pricing trends in different areas, management can gain valuable insights for setting an appropriate and successful approximate price range for their new restaurant in a specific location.

4.3 Maintaining customer satisfaction levels

Maintaining customer satisfaction levels is paramount for new restaurants as it directly influences their success and long-term viability. Satisfied customers are more likely to become repeat customers, recommend the restaurant to others, and leave positive reviews, which can significantly contribute to the establishment's reputation and overall growth (Vajjhala & Ghosh, 2022). However, ensuring customer satisfaction can be highly challenging for new restaurants. They face various hurdles, such as establishing a solid reputation, meeting customer expectations, and managing operational complexities (Bilgihan et al., 2018). Building a positive reputation takes time and effort, as new restaurants need to prove themselves to a skeptical audience. They must strive to exceed customer expectations from the moment they open their doors, as first impressions are vital in shaping customers' perceptions (Lee & Kim, 2020). Any shortcomings or inconsistencies in the restaurant can result in dissatisfied customers and negative reviews, which can be detrimental to the restaurant's success (Vajjhala & Ghosh, 2022).

Analyzing online ratings of existing restaurants can provide new restaurants with valuable insights to solve various problems and improve their chances of success in the competitive industry. Data analysis of online ratings of existing restaurants allows new restaurants to gain a comprehensive understanding of customer preferences and expectations (Bilgihan et al., 2018; Vajjhala & Ghosh, 2022). By examining positive reviews, new establishments can identify the aspects of their competitors' offerings that are highly praised by customers (Lee & Kim, 2020). This insight enables them to replicate successful elements, such as popular dishes, outstanding service, or unique ambiance, in their own establishment. Understanding what customers value most in their dining experience helps new restaurants tailor their offerings to meet those expectations and create a competitive advantage (Bilgihan et al., 2018; Vajjhala & Ghosh, 2022). On the other hand, studying negative reviews in online ratings provides new restaurants with crucial information about the shortcomings and weaknesses of their competitors. By analyzing common complaints or issues raised by customers, new establishments can proactively address those areas and ensure they do not make the same mistakes.

Using Descriptive Statistics and a Bar Chart, an average online rating of 3.6-3.7 is observed from the data. The average online rating serves as an indicator of customer satisfaction and

perception of the dining experience in Bangalore. By analyzing the average rating, new restaurants can gauge the overall quality and competitiveness of the local restaurant scene. This information will help understand the expectations and preferences of the local customer base. Furthermore, it enables new restaurants to set realistic benchmarks and goals for their own performance, aiming to meet or exceed the average rating to attract and retain customers in the competitive landscape.

Figure 15,16
Descriptive Statistics of Ratings
Bar Chart of Average Ratings of restaurants (Self-drawn using Qlik)

the other hand, analyzing the data of online rating vote count of existing restaurants is important for a new restaurant as it provides insights into the popularity and reputation of competitors in the area. By examining the vote count, new restaurants can gauge the level of customer engagement and the extent to which customers are actively reviewing and rating restaurants in the locality. This information helps them understand the level of competition and the potential visibility and impact of online reviews in their target market, allowing them to develop effective strategies to attract and engage customers based on their online

reputation management. A Bar Chart (Figure 17) was drawn using Qlik to help identify restaurants with the most vote count in Bangalore.

Figure 17
Vote Count Bar Chart (Self-drawn using Qlik)

Furthermore, analyzing the data of the highest and lowest-rated restaurants using a tree map, as shown in Figures 18 and 19, can be helpful for the new restaurant by providing a visual representation of the competitive landscape. The tree map will allow the new restaurant to identify the key players in the market and understand the factors that contribute to their success or shortcomings. By examining the characteristics and customer feedback of the highest and lowest rated establishments, the new restaurant can gain valuable insights to shape their own business strategy and differentiate themselves in the market to attract and satisfy customers.

Figure 18
Highest Rated Restaurants Tree Map (Self-drawn using Qlik)

Figure 19

Lowest Rated Restaurants Tree Map (Self-drawn using Qlik)

Overall, leveraging data analysis of online ratings of existing restaurants empowers new establishments to make informed decisions and optimize their operations. By understanding customer preferences, addressing weaknesses in the industry, and fulfilling unmet needs, new restaurants can enhance their chances of success and build a loyal customer base from the start. This strategic approach based on data analysis allows them to differentiate themselves from competitors, provide a superior dining experience, and ultimately thrive in a highly competitive industry.

5. Conclusion

In conclusion, leveraging business analytics can significantly benefit aspiring restaurant owners in making informed decisions when opening a new restaurant in Bangalore. By analyzing comprehensive data from sources like Zomato, restaurant owners can gain valuable insights into the market landscape, customer preferences, and industry trends. This article highlighted three key challenges restaurant management faces: choosing the location and restaurant type, price management, and maintaining customer satisfaction levels.

Each of these challenges has been addressed through the application of business analytics techniques. For selecting the optimal location and restaurant type, tools such as bar charts, chi-square test, and Mekko charts have been utilized to identify areas with high restaurant density, understand the association between location and restaurant type, and identify the top restaurant types in specific locations. These insights enable restaurant owners to position their

new restaurants strategically, align with customer preferences, and maximize their chances of success.

Price management, another crucial aspect, has been tackled through market research, analysis of pricing strategies, chi-square test, and line charts. By understanding the target market, considering the restaurant's positioning, and analyzing pricing trends in different areas, restaurant owners can establish an appropriate and profitable price range that attracts customers and reflects the restaurant's value proposition.

Finally, maintaining customer satisfaction levels has been addressed by analyzing online ratings and reviews. By examining positive reviews, new establishments can identify successful elements in their competitors' offerings and replicate them in their own establishment. Analyzing negative reviews helps identify areas for improvement and allows proactive measures to address customer concerns and ensure a positive dining experience.

By leveraging business analytics, aspiring restaurant owners can make data-driven decisions that mitigate risks, position their new restaurant strategically, set competitive prices, and meet customer expectations. These insights contribute to the restaurant's overall success, growth, and profitability in the dynamic and competitive restaurant landscape of Bangalore. In an industry where informed decision-making is crucial, business analytics offers valuable tools and techniques to gain a competitive edge and ensure long-term success in the vibrant restaurant scene of Bangalore.
